\section*{ARTICLE INFO}

Keywords: 5-DOF Parallel Mechanisms, Three translation and two independent rotations (3T2R), Study parameters, General and first-order kinematic mapping, Forward Kinematic Problem (FKP), Constant-position workspace.

\section*{ABSTRACT}

The main objective of this paper is to study the Euclidean displacement of a 5-DOF parallel mechanism performing three translation and two independent rotations with identical limb structures—recently revealed by performing the type synthesis—in a higher dimensional projective space, rather than relying on classical recipes, such as Cartesian coordinates and Euler angles. In this paper, Study's kinematic mapping is considered which maps the displacements of three-dimensional Euclidean space to points on a quadric, called Study quadric, in a seven-dimensional projective space, $\mathbb{P}^7$. The main focus of this contribution is to lay down the essential features of algebraic geometry for our kinematics purposes, where, as case study, a 5-DOF parallel mechanism with identical limb structures is considered. The forward kinematic problem is reviewed and the kinematic mapping is introduced for both general and first-order kinematics, i.e., velocity, which provides some insight into the better understanding of the kinematic behaviour of the mechanisms under study in some particular configurations for the rotation of the platform and also the constant-position workspace.

1. Introduction

The kinematic analysis of parallel mechanisms requires a suitable mathematical framework in order to describe both translation and rotation in a most general way. This can be achieved by resorting to algebraic geometry\cite{1}. The fundamental concept of relating mechanical structures, including parallel mechanisms, with algebraic varieties is called Study's kinematic mapping. This mapping associates to every Euclidean displacement in $SE(3)$, $\gamma$, a point $c$ on a subset of a real projective space $\mathbb{P}^7$, called the Study quadric $S_6^2 \subset \mathbb{P}^7$ \cite{2, 3}. This subject, i.e., algebraic geometry, occupies a central place in modern mathematics and has multiple conceptual connections with such diverse fields as geometric design, coding theory and mechanisms and robotics. Our interest toward combining and then applying algebraic geometry and Study's kinematic mapping to the kinematic analysis is twofold:

1) Using the superabundance of variables which eliminates the need to resort to trigonometric expressions and produces homogeneous equations;

2) As opposed to formulations based on three-dimensional Euclidean space, algebraic geometry provides a better understanding of the kinematic properties of mechanisms.

Returning to the kinematic analysis of parallel mechanisms, this paper aims first at establishing the relations which allow the general and first-order kinematic mapping of three-dimensional Euclidean space to the Study parameters and then the Forward Kinematic Problem (FKP) for the topologically symmetric 5-DOF parallel mechanisms performing a specific motion patterns which are described in what follows. In general, 5-DOF parallel mechanisms are a class of parallel mechanisms with reduced degrees of freedom which, according to their mobility, fall into three classes \cite{4}:

1) Three translational and two rotational freedoms (3T2R);

2) Three rotational and two planar translational
freedoms (3R2T_p):
   a) (3R2T'_p) with instantaneous planar motion;
   b) (3R2T''_p) with fixed planar motion;

3) Three rotational and two spherical translational freedoms (3R2T_p).

For the 5-DOF parallel mechanisms, this paper deals with the first one, i.e., the one performing 3TR motion pattern. Geometrically, the 3TR motion can be made equivalent to guiding a combination of a directed line and a point on it. Accordingly, the 3TR mechanisms can be used in a wide range of applications for a point-line combination including, among others, 5-axis machine tools [5, 6], welding and conical spray-gun. In medical applications that require at the same time mobility, compactness and accuracy around a functional point, 5-DOF parallel mechanisms can be regarded as a very promising solution [7].

Based on the results obtained from type synthesis and the recent study conducted in [8-11], two kinematic arrangements may be of practical interest for symmetric 5-DOF parallel mechanisms (3TR2), namely: 5-PRU [10] and 5-PRUR [8, 9]. In this paper, as a case study, we consider 5-PRUR. Here and throughout this paper, P stands for a prismatic joint R for a revolute joint and U for an universal joint. To distinguish the actuated joint from a non-actuated one, which is referred to as passive joint, the actuated one is underlined, for instance P. It should be noted that the FKP of 5-DOF parallel mechanisms (3TR2) was solved in [10, 12]. The latter study revealed that this kind of mechanisms have up to 1680 finite solutions and for a simplified design a 27-dimensional projective space, \( \mathbb{P}^7 \) [3]. The homogeneous coordinates of a point in \( \mathbb{P}^7 \) are given by \( s = (x_0 : x_1 : x_2 : x_3 : y_0 : y_1 : y_2 : y_3) \). The kinematic pre-image of \( s \) is the displacement \( \gamma \) described by the transformation matrix:

\[
\Omega^{-1} H = \begin{bmatrix}
H & 0 & 0 & 0 \\
p & x_0^2 + x_1^2 + x_2^2 + x_3^2 & 2(x_0x_1 + y_0y_1 + z_0z_1) & 2(x_0 + y_0 + z_0) \\
q & 2(x_0x_1 + y_0y_1 + z_0z_1) & x_0^2 + x_1^2 + x_2^2 + x_3^2 & 2(x_0x_1 + y_0y_1 + z_0z_1) \\
r & 2(x_0x_1 + y_0y_1 + z_0z_1) & 2(x_0x_1 + y_0y_1 + z_0z_1) & x_0^2 + x_1^2 + x_2^2 + x_3^2
\end{bmatrix}
\]

where

\[
H = x_0^2 + x_1^2 + x_2^2 + x_3^2, \quad p = 2(-x_0y_1 + x_1y_0 - x_2y_3 + x_3y_2), \\
q = 2(-x_0y_1 + x_1y_0 + x_2y_3 - x_3y_2), \\
r = 2(-x_0y_1 - x_1y_0 + x_2y_3 + x_3y_2).
\]

Note that the lower right three by three sub-matrix is a proper orthogonal matrix if:

\[
x_0y_0 + x_1y_1 + x_2y_2 + x_3y_3 = 0,
\]

and not all \( x_j \) are zero. If these conditions are fulfilled \((x_0 : \ldots : y_3)^T \) are called Study parameters of the displacement \( \gamma \). Equation (4) defines a quadric, the so-called Study quadric, \( S^2_s \), which lies on a seven-dimensional kinematic space, \( \mathbb{P}^7 \). Thus the range of the kinematic mapping is the Study quadric, \( S^2_s \), minus the three dimensional subspace defined by:

\[
E_{s} : x_0 = x_1 = x_2 = x_3 = 0.
\]

\( S^2_s \) is called Study quadric and \( E_{s} \) is the exceptional or absolute generator. One can normalize the parameters such that \( H = 1 \), then the coordinate \( x_0 \) represents the cosine of the half rotation angle. Note that there are other possibilities to normalize.

Reaching this step, the prime concern is with obtaining the correspondence between the Study parameters and the component of a given matrix which represents the motion of a rigid body. Let \( A = [a_{ij}]_{i=0...4} \) be this general matrix which can be obtained using the D-H convention. This mapping consists in re-parametrization of the Euclidean displacements using algebraic parameters. It should be noted that the quadruple \( x = (x_0 : x_1 : x_2 : x_3) \) is known as the Euler
parameters and the best way, i.e., free of parametrization singularity, of computing the Euler parameters was already known to Study [2]. He demonstrated that for any Euclidean transformation, in this case $A$, the homogeneous quadruple $x = (x_0 : x_1 : x_2 : x_3)$ can be obtained from at least one of the following proportions:

$$\begin{align*}
&x_0 : x_1 : x_2 : x_3 = \\
&= \frac{a_0 + a_1 + a_2 + a_3 + a_4 + a_5 - a_1 - a_2}{2} \\
&= \frac{a_2 - a_3 - 1 + a_1 - a_2 - a_3 + a_4 - a_1 - a_3}{2} \\
&= \frac{a_3 - a_1 - a_2 - a_4 - a_5 + a_1 + a_3 + a_5}{2} \\
&= \frac{a_1 - a_2 - a_3 + a_4 - a_2 + a_3}{2}
\end{align*}
$$

(6)

It can be shown that all four proportions are valid representations [15]. In fact, each proportion is not singular-free per se. However, the set as a whole is free of any parametrization singularity. The singularity for any Euclidean transformation, in this case $A$, can be computed from:

$$
\begin{bmatrix}
\cos \theta & \sin \phi & \sin \phi & \cos \phi & \sin \theta \\
0 & \cos \phi & \sin \phi & -\sin \phi & \\
-\sin \theta & \sin \phi \cos \phi & \cos \phi \cos \theta & \cos \phi \sin \theta & \end{bmatrix}
$$

(8)

Vectors $e_1$ and $e_2$ are unit vectors respectively along the first and last revolute joints of each leg. They are the same for all leg, by construction. We define respectively $
\vec{p} = [x, y, z]^T$ as the reference point $p$ of the platform velocity and the angular velocity of the mobile platform.

This mechanism consists of an end-effector which is linked by 5 identical limbs of the RPUR type to a base. The input of the mechanism is provided by the five linear prismatic actuators. From the type synthesis presented in [17], the geometric characteristics associated with the components of each leg are as follows: The five revolute joints attached to the platform (the last R joint in each of the legs) have parallel axes, the first two revolute joints of each leg have parallel axes and the last two revolute joints of each leg have parallel axes. It should be noted that the second and third revolute joints in each leg are built with intersecting and perpendicular axes and are thus assimilated to U joints. Further results regarding the kinematic properties, such as the solution of the IKP, FKP and the determination of the constant-orientation workspace can be found in [10, 12, 18].
\[ F_p(s) = 8(\phi^2 + \phi(\gamma(\gamma - 1)) + 8(\phi^2 - \phi(\gamma - 1)) - x_0 x_1 + x_2 x_3 \] 
\[ + 14(\phi^2 - \phi(\gamma - 1)) + (\phi^2 - \phi(\gamma - 1)) x_3 - x_1 x_2) = 0. \]
\[ C = x_0^2 - x_1^2 - x_2^2 + x_3^2 = 0. \]

Moreover, from the latter studies, 1680 finite solutions were found for the FKP where for a given design and input parameters 208 real solutions was reported (This is not an upper bound for the number of the real solutions). However, there are still some gaps for the general and first-order kinematic mapping of such mechanisms which is the subject of the following sections.

C. Mapping between Study Parameters and Three-dimensional Euclidean Space

In this section, we attempt to set up correspondences between the Study parameters and the three dimensional Euclidean space and vice versa. These transformations can be used to convert the solutions obtained for the FKP which are explored in projective space, i.e., Study parameters, in order to ensure their validity and to provide a physical sense to the solutions.

1) Cartesian representation of Study’s parameters:

Mathematically, the mapping from an element of \( P^7 \), \( s \in P^7 \), into a three-dimensional real vector space, called Euclidean three space, \( SE(3) \), is defined as:
\[ m_i : P^7 \mapsto SE(3), \quad s \mapsto m_i(s), \quad m_i(s) \in R^S. \quad (11) \]
where \( R^S \) stands for the five-dimensional real array space representing the three translations and two permitted rotational DOFs. The first step is to compute the rotational DOFs \( (\phi, \theta) \). To this end, the lower three by three sub matrix of \( \Omega \), leads to a unique solution for \( \phi \) and \( \theta \), namely:
\[ \theta = \arctan 2 (x_1 x_2 + x_0 x_3, x_2 x_1 - x_0 x_2), \quad (12) \]
\[ \phi = \arctan 2 (x_0 x_1 + x_0 x_2, x_1 x_2 - x_0 x_1). \quad (13) \]

To compute the position of the platform, \( p = [x_0, y_0, z_0]^T \), for a given set of \( x = [x_0, \gamma, x_3, \gamma, x_1, \gamma, x_2, \gamma, x_3, \gamma, x_1, \gamma, x_2]^T \) obtained above, one should use the following [15]:
\[ 2y_0 = x_0 x + x_0 y + x_0 z, \quad 2y_1 = -x_0 x + x_1 z - x_0 y, \]
\[ 2y_2 = x_0 y - x_0 z + x_1 y, \quad 2y_3 = -x_0 z + x_1 y - x_0 y. \quad (14) \]

One could consider any three equations in order to obtain a unique set of solutions for \((x_1, y, z)\) for a given \( s \). By considering the first four equations it results that the determinant of this system of equations is:
\[ x_3 (x_0^2 + x_1^2 + x_2^2 + x_3^2). \quad (15) \]

For the considered system of equations, once \( x_3 = 0 \) the system of equations degenerates. Using the fact that this system of equation is overdetermined, one can establish another system of equations which avoids this singular condition. For instance in the previous case when \( x_3 = 0 \) one could consider a system of equations in which the first equation is replaced by the fourth one and the determinant becomes:
\[ x_0 (x_0^2 + x_1^2 + x_2^2 + x_3^2). \quad (16) \]

It follows that when \( x_3 = 0 \) then \( x_0 = \pm \sqrt{\frac{2}{2}} \) and the system of equations is of full rank. Once the latter system of equations is solved for \((x, y, z)\) the position of the platform, \( p \), with respect to the base frame presented in Fig. 1(a) becomes:
\[ p = [y, z, x]^T. \quad (17) \]

Following the same procedure, one can transform the vectors describing the geometry of the base and platform, written in terms of Study's parameters, \( b_i = [b_{i_1}, \ldots, b_{i_6}] \) and \( m_i = [m_{i_1}, \ldots, m_{i_6}] \), respectively, into the vectors describing them in the Cartesian coordinates, \( r_i \) and \( s' \) (See Fig. 1).

Skipping the mathematical derivations one obtains:
\[ r_i = [-2b_{i_1}, -2b_{i_2}, -2b_{i_3}]^T, \quad s' = [-2m_{i_1}, 2m_{i_2}, -2m_{i_3}]^T. \quad (18) \]

It is recalled that due to the parallelism of the axes attached to the base and platform, one has:
\[ b_{i_1} = b_{i_2} = b_{i_3} = b_{i_4} = 0 \quad \text{and} \quad m_{i_1} = m_{i_2} = m_{i_3} = m_{i_4} = 0. \]

2) Representation of Study’s Parameters in Terms of Three-dimensional Euclidean Space: Mathematically, the mapping from an element of \( SE(3) \), \( k \in R^S \), into seven-dimensional space, \( P^7 \), is defined as:
\[ m_k : SE(3) \mapsto P^7, \quad \kappa \mapsto (m_k(\kappa) \equiv s). \quad (19) \]

The mapping from Cartesian space to Study's parameters requires further mathematical manipulations. Without loss of generality, assume the homogeneous condition to be:
\[ \sum_{i=0}^{3} x_i = x_0^2 + x_1^2 + x_2^2 + x_3^2 = 1 \quad (20) \]

From Eqs. (12) and (13) it follows that:
\[ 4x_1 x_3 = \cos \phi \sin \theta, \quad 4x_1 x_3 = \sin \phi \cos \phi. \quad (21) \]

Squaring both sides of the above expressions and adding them results in:
\[ 16x_1^2 (x_1^2 + x_2^2) = 2 + 2 \sin (\phi + \theta). \quad (22) \]

Combining the homogeneous and constraint equation, Eq. (10), one has:
\[ x_1^2 + x_2^2 = \frac{1}{2}, \quad x_0^2 + x_3^2 = \frac{1}{2}, \quad (23) \]

where one can obtain the following for and \( x_0 \) and \( x_1 \):
\[ x_1 = (-1)^{\delta_1} \sqrt{\frac{1 + \sin (\phi + \theta)}{2}}, \quad x_0 = (-1)^{\delta_2} \sqrt{\frac{1 - \sin (\phi + \theta)}{2}}. \quad (24) \]

In the above, \( \delta_1 \in [0,1] \) and \( \delta_2 \in [0,1] \) stand for the two distinct solutions. As it can be observed from the above, this mapping admits two distinct solutions for \( x_1 \) and \( x_0 \) for a given pose of the platform in the
Cartesian space. These two distinct solutions can be classified as follows: (a) \( \theta \phi > 0 \) then \( \delta_1 = \delta_2 \) and (b) \( \theta \phi \leq 0 \) then \( \delta_1 \neq \delta_2 \). Handling the values for \( x_0 \) and \( x_3 \) and substituting into Eq. (12) leads to:

\[
\cos \theta = x_1 x_4 + x_0 x_2, \quad \sin \theta = x_2 x_0 - x_0 x_1, \tag{25}
\]

which, once solved for \( x_1 \) and \( x_2 \) yield:

\[
x_1 = (x_3 \cos \theta - x_0 \sin \theta), \quad x_2 = (x_3 \sin \theta + x_0 \cos \theta). \tag{26}
\]

The transformation for the fixed parameters \( r_i \) and \( s'_i \), vector representing respectively the geometry of the base and platform as depicted in Fig. 1, can be readily obtained using Eq. (18). The rotational parameters, i.e., \( x \) and \( y = [y_0, y_1, y_2, y_3] \) can be found by back substitution into Eq. (14).

Thus from above it follows that the mapping from the Study parameters to the Cartesian space is one to one and the converse, i.e., from Cartesian space to Study’s parameters is two to one. This is called double covering of the Euclidean displacement group SE(3). For example: The dual quaternions are a double covering of SE(3).

\[\text{D. First-order Kinematic Mapping and Different sets in } P^7 \text{ for describing } \dot{\mathbf{x}} \dot{\mathbf{x}}\]

We direct our attention to a formulation based on the projective space which leads to define different sets in order to fully determine the Study parameters and their corresponding time rate of change. Combining the homogeneous and constraint condition leads to:

\[
x_0^2 + x_1^2 = \frac{1}{2}, \quad x_2^2 + x_3^2 = \frac{1}{2}. \tag{27}
\]

Differentiating the above with respect to time results in:

\[
x_0 \dot{x}_0 + x_1 \dot{x}_1 = 0, \quad x_2 \dot{x}_1 + x_3 \dot{x}_2 = 0. \tag{28}
\]

Then, combining the above with Eqs. (27) leads to the following system of equations:

\[
\begin{align*}
x_0 \dot{x}_0 + x_1 \dot{x}_1 &= 0, \quad x_1 \dot{x}_1 + x_2 \dot{x}_2 = 0, \\
x_2^2 + x_3^2 &= \frac{1}{2}, \quad x_1^2 + x_2^2 = \frac{1}{2}
\end{align*} \tag{29}
\]

The above allows to conclude that prescribing \( \dot{\mathbf{x}} = [\dot{x}_0 : \dot{x}_1 : \dot{x}_2 : \dot{x}_3] \) results in two solutions to \( \mathbf{x} \):

\[
\begin{align*}
x_0 &= \frac{\pm \sqrt{2}}{2} \frac{\dot{x}_1}{\sqrt{\dot{x}_1^2 + \dot{x}_3^2}}, & x_1 &= \frac{\pm \sqrt{2}}{2} \frac{\dot{x}_2}{\sqrt{\dot{x}_1^2 + \dot{x}_2^2}}, \\
x_2 &= \frac{\pm \sqrt{2}}{2} \frac{\dot{x}_0}{\sqrt{\dot{x}_0^2 + \dot{x}_1^2}}, & x_3 &= \frac{\pm \sqrt{2}}{2} \frac{\dot{x}_2}{\sqrt{\dot{x}_0^2 + \dot{x}_2^2}} \tag{30}
\end{align*}
\]

From Eq. (29), one can define different sets to fully determine \( \mathbf{x} \dot{\mathbf{x}} = [\mathbf{x} \dot{\mathbf{x}}] \). In order to obtain these sets, we define \( X_{p1} \) and \( X_{p2} \) respectively as the set of parameters which allow to solve the first and second system of equations presented in Eq. (29) as follows:

\[
X_{p1} = \{[x_0, \dot{x}_0], [x_1, \dot{x}_1], [x_2, \dot{x}_2], [x_3, \dot{x}_3]\}, \tag{31}
\]

\[
X_{p2} = \{[x_1, \dot{x}_1], [x_2, \dot{x}_2], [x_3, \dot{x}_3]\}, \tag{32}
\]

Consequently, a set, called \( X_p \), which is the two-by-two combination of components of \( X_{p1} \) and \( X_{p2} \) allows to fully determine \( \mathbf{x} \dot{\mathbf{x}} \) and is formulated as follows:

\[
X_p = (X_{p1} \cup X_{p2})^2 \cup [\dot{x}_0, \dot{x}_1, \dot{x}_2, \dot{x}_3]. \tag{33}
\]

Thus it can be inferred that 21 different sets exist in order to fully determine \( \mathbf{x} \) and \( \dot{\mathbf{x}} \). It follows that the rotation and angular velocity of the mobile platform can be fully prescribed either by prescribing all the time derivatives of the Study parameters, \( \mathbf{x} \), or by a combination of some Study parameters and their time derivatives, \( (X_{p1} \cup X_{p2})^2 \).

\[\text{E. First-order Kinematic Mapping for the Angular Velocity}\]

Here, we direct our attention to the mapping of the first-order kinematics from the time derivative of the Study parameters, \( \mathbf{x} \) and \( \dot{y} = [y_0, y_1, y_2, y_3] \), to the velocity and angular velocity \( \dot{\mathbf{p}} = [\dot{x}, \dot{y}, \dot{z}]^T \) and \( \omega \).

1) Mapping of the Time Derivative of Three-dimensional Euclidean Space to Study’s Parameters:

Referring to Eq. (24) and upon differentiating with respect to time, and skipping mathematical derivations, one has:

\[
\dot{x}_1 = (-1)^i \frac{\dot{\theta} + \phi}{8x_2} \cos(\theta + \phi). \tag{34}
\]

As it can be observed, the above fails to result in a solution for \( \dot{x}_3 \) when \( 1 + \sin(\theta + \phi) = 0 \) which in the projective space corresponds to a configuration for which \( x_3 = 0 \). In order to avoid such a configuration the corresponding value for \( \cos(\theta + \phi) \) should be found by referring to Eq. (22):

\[
\cos(\theta + \phi) = \pm 2 \sqrt{2} x_1 \sqrt{1 - 2x_2^2}. \tag{35}
\]

Upon substituting the above into Eq. (34) and replacing the corresponding expression found for \( \dot{x}_3 \) in Eq. (24) leads to:

\[
\dot{x}_3 = (-1)^i \frac{\dot{\theta} + \phi}{4} \sqrt{1 - \sin(\theta + \phi)}, \tag{36}
\]

which is obviously singularity-free. Following the same reasoning it follows that:

\[
\dot{x}_3 = (-1)^i \frac{\dot{\theta} + \phi}{4} \sqrt{1 + \sin(\theta + \phi)}. \tag{37}
\]

Upon differentiating Eq. (26) with respect of time one could obtain the relations which map the three-dimensional Euclidean space to \( \dot{x}_1 \) and \( \dot{x}_2 \). The following can be obtained:
\[
\dot{x}_1 = \dot{x}_3 \cos \theta - \dot{\theta} x_2 \sin \theta - \dot{x}_0 \sin \theta - \dot{\theta} x_3 \cos \theta, \quad (38)
\]
\[
\dot{x}_2 = \dot{x}_3 \sin \theta + \dot{\theta} x_1 \cos \theta + \dot{x}_0 \cos \theta - \dot{\theta} x_3 \sin \theta. \quad (39)
\]

It should be noted in the above that one should use respectively Eqs. (36) and (37) for the mapping of \( \dot{x}_3 \) and \( \dot{x}_0 \) and Eq. (24) for \( x_2 \) and \( x_0 \).

2) Mapping of the Time Derivative of the Study Parameters to the Three-dimensional Euclidean Space:

From Eq. (12) it follows that:
\[
-\dot{\theta} \sin \theta = (\dot{x}_3 x_1 + \dot{x}_3 x_0 + \dot{x}_0 x_1 + \dot{x}_0 x_0), \quad (40)
\]
\[
\dot{\theta} \cos \theta = (\dot{x}_2 x_1 + \dot{x}_2 x_0 - \dot{x}_3 x_1 + \dot{x}_3 x_0). \quad (41)
\]

Squaring both sides and then adding leads to:
\[
\dot{\theta}^2 = 2(\dot{x}_3 x_1 + \dot{x}_3 x_0 + \dot{x}_0 x_1 + \dot{x}_0 x_0)^2 + (\dot{x}_2 x_1 + \dot{x}_2 x_0 - \dot{x}_3 x_1 + \dot{x}_3 x_0)^2. \quad (42)
\]

A similar approach yields to the following for \( \dot{\phi} \):
\[
\dot{\phi} = 2((\dot{x}_3 x_1 + \dot{x}_3 x_0 + \dot{x}_0 x_1 + \dot{x}_0 x_0)^2 + (\dot{x}_2 x_1 + \dot{x}_2 x_0 - \dot{x}_3 x_1 + \dot{x}_3 x_0)^2). \quad (43)
\]

where, finally, upon skipping some mathematical manipulations, one has:
\[
\dot{\theta} = \pm \sqrt{2(\dot{x}_3 x_1 + \dot{x}_3 x_0 + \dot{x}_0 x_1 + \dot{x}_0 x_0)^2 + (\dot{x}_2 x_1 + \dot{x}_2 x_0 - \dot{x}_3 x_1 + \dot{x}_3 x_0)^2}. \quad (44)
\]
\[
\dot{\phi} = \pm \sqrt{2((\dot{x}_3 x_1 + \dot{x}_3 x_0 + \dot{x}_0 x_1 + \dot{x}_0 x_0)^2 + (\dot{x}_2 x_1 + \dot{x}_2 x_0 - \dot{x}_3 x_1 + \dot{x}_3 x_0)^2)}. \quad (45)
\]

F. First-order Kinematic Mapping for the Point Velocity

The relations allowing the mapping of angular velocity from the projective space into the three-dimensional Euclidean space, and vice versa, can be readily extended to obtain the mapping for the translational velocity. This can be done by differentiating Eq. (14) with respect of time.

G. From three-dimensional Euclidean Space to Study’s Parameters

In this case the pose of the platform, \((x, y, z, \phi, \theta)\) and the time rate of change of its coordinates, \((\dot{x}, \dot{y}, \dot{z}, \dot{\phi}, \dot{\theta})\) are given. Upon differentiating Eq. (14) with respect to time one could readily find \(\dot{\mathbf{y}}\).

H. From Study’s Parameters to the Three-dimensional Euclidean Space

In this case the time derivative of Eq. (14) with respect to time should be solved for \((\dot{x}, \dot{y}, \dot{z})\) by having in hand \(\mathbf{s}\), \(\mathbf{x}\) and \(\dot{\mathbf{y}}\). Finally, based on Eq. (17), it follows that:
\[
\mathbf{p} = [\dot{y}, \dot{z}, \dot{x}]^T. \quad (46)
\]

It should be noted that in the case that the above system of equation is rank deficient one should proceed as explained in section 2.3.2.1. As a consequence the above mappings are both singularity-free.

4. Some Applications of Kinematic Mapping

Generally, in the context of parallel mechanisms, the study kinematic mapping is used to investigate the FKP and due to its mathematical complexities, initiated several researches both in mathematics and mechanics.

From the begining of this section some insight was given for the FKP of the 5-DOF parallel mechanism under study where for the next mechanism more details will be provided. In what follows, we resort to Study kinematic mapping in order to first explore some kinematic properties of the 5-DOF parallel mechanism under study for some particular rotational configurations, which cannot be obtained by entailing the study in three-dimensional Euclidean space. Then, a subset of workspace, called the constant-position workspace, is elaborated.

A. Particular Configurations for the Kinematic Mapping of 5-RPUR Parallel Mechanisms

As stated before, the sets belonging to \(X_p\) may fail to fully determine \(\mathbf{x}\). These configurations are treated hereafter for \([\dot{x}_0, \dot{x}_1, \dot{x}_2, \dot{x}_3]\) and the set belonging to

\[
(X_{p1} \cup X_{p2})^2. \quad (46)
\]

It should be noted that these configurations should not be interpreted as singular configurations and that there are configurations which admit infinitely many solutions.

1) Particular configuration for \([\dot{x}_0, \dot{x}_1, \dot{x}_2, \dot{x}_3]\):

In general for a given \(\mathbf{x}\), which stands for the angular velocity of the platform, one can readily determine its corresponding \(\mathbf{x}\). In fact, if \(\mathbf{x}\) is prescribed then one could readily find \(\mathbf{x}\) from Eq. (30) and also \(\dot{\theta}\) and \(\dot{\phi}\) respectively from Eqs. (44) and (45). Then having \(\mathbf{x}\) by using Eqs. (12) and (13) leads to obtaining \(\dot{\theta}\) and \(\dot{\phi}\). This means that \(\mathbf{x}\) is the central quantity of the mapping. This issue is depicted in Fig. 2. As it can be observed from the latter tree-model having in place \(\mathbf{x}\) allows to find \(\mathbf{x}\), \((\dot{\phi}, \dot{\theta})\) and \((\dot{\phi}, \dot{\theta})\). As mentioned above there are some configurations for which the mapping would have infinitely many solutions. Inspecting Eq. (30) it follows that in the following case the mechanism would have infinitely many solutions for the rotational DOF:

\[
[\dot{x}_0, \dot{x}_1] = [0, 0] \rightarrow \dot{\theta} + \dot{\phi} = 0, \quad (47)
\]
\[
[0, 0] \rightarrow \dot{\theta} - \dot{\phi} = 0, \quad (48)
\]
\[
[0, 0, 0, 0] \rightarrow \dot{\theta} = \dot{\phi} = 0. \quad (49)
\]
angular velocity as given above, can be produced for any of the orientations of the mechanism.

2. Particular configuration for \((X_{p1} \cup X_{p2})^2\):

In this case, for a configuration in which one of the Study parameters becomes zero, then it would impossible to fully determine \( \mathbf{x} \). Let's consider respectively the first and third component of \( X_{p1} \) and \( X_{p2} \) which results in \([x_0, x_2, \hat{x}_0, \hat{x}_2]\). In the case that \( x_0 = 0 \) then \( \hat{x}_0 \), and as consequence \( \mathbf{x} \), may have infinitely many solutions. These configurations and their influences in both projective space and three-dimensional Euclidean space can be summarized as follows:

\[
x_0 = 0 \rightarrow \hat{x}_3 = 0, \quad \theta + \phi = \frac{\pi}{2},
\]

\[
x_1 = 0 \rightarrow \hat{x}_2 = 0, \quad \theta - \phi = -\frac{\pi}{2},
\]

\[
x_2 = 0 \rightarrow \hat{x}_1 = 0, \quad \theta - \phi = \frac{\pi}{2},
\]

\[
x_3 = 0 \rightarrow \hat{x}_0 = 0, \quad \theta + \phi = -\frac{\pi}{2}.
\]

The above configurations can be interpreted as follows: the mechanism is able to perform any angular velocity for \( \hat{\theta} \) and \( \hat{\phi} \).

B. Constant-position Workspace

This subset of workspace consists of the feasible orientations of the platform for a prescribed position of the platform. Usually, it is very cumbersome to assess geometrically such a workspace and it is preferable to perform this analysis using numerical methods. In three-dimensional Euclidean space, this can be formulated as obtaining intervals for \( \hat{\theta} \) and \( \hat{\phi} \) for which all the actuators satisfy the stroke limits. It should be noted that the constant-orientation workspace was investigated in detail [19] where Bohemian domes came up for the vertex space.

It should be noted that the analysis of the constant-position workspace in three-dimensional Euclidean space is a delicate task. Figure 3 represents the constant-position workspace for a 5-RPUR parallel mechanism for a given position which is plotted in a two-dimensional Cartesian coordinates.

It would be more advantageous and enlightening to explore such a problem in seven-dimensional kinematic space and by resorting to the kinematic mapping presented previously it can be readily converted into three-dimensional Euclidean space. Moreover, this approach results in a meaningful representation of the orientation workspace, which is an angular travel around a circle, Fig. 4. Usually, the results of constant-orientation workspace are plotted in a Cartesian space which is more meaningful for the position purpose and few appropriate environments have been reported in the literature for the constant-position workspace, for instance the study elaborated in [20] for spatial parallel mechanisms. To follow the proposed approach, the given position of the platform should be expressed in terms of Study parameters. This can be achieved using Eq. (14) which is recalled here:

\[
2y_0 = x_0x + x_2y + x_3z, \quad 2y_1 = -x_0x + x_2z - x_3y, \quad 2y_2 = -x_0y + x_1z + x_3x, \quad 2y_3 = -x_0z + x_1y - x_3x.
\]

For a given position vector \((x, y, z)\) and upon substituting the \( y \) obtained from the above relations into \( F_p \), one obtains an expression which is a function of only \( x \) and \( \rho_p \). To be consistent with the number of permitted orientational DOFs, based on Eq. (27), the following substitution can be done into \( F_p(x) \) which results in only two unknowns, namely \( \varepsilon \) and \( \xi \) in trigonometric forms:

\[
x_0 = \frac{\sqrt{2}}{2} \cos \varepsilon, \quad x_3 = \frac{\sqrt{2}}{2} \sin \varepsilon,
\]

\[
x_1 = \frac{\sqrt{2}}{2} \cos \xi, \quad x_2 = \frac{\sqrt{2}}{2} \sin \xi.
\]
It should be noted that the obtained solutions for $\varepsilon$ and $\xi$ cannot be plotted along the two constraint circles since they are not decoupled. To do so, we use a spherical representation which is notationally depicted in Fig. 4. Then by applying the tan-half substitution for $\varepsilon_i = \tan \left( \frac{\varepsilon}{2} \right)$ and $\xi_i = \tan \left( \frac{\xi}{2} \right)$, one obtains:

$$^0 F_p (\varepsilon, \xi, \rho_p) = 0.$$  

The above corresponds to the principal limb and applying the same procedure explained in [12] for obtaining the forward kinematic expressions for other limbs, one can readily find the corresponding expressions for the other four limbs:

$$^0 F_j (\varepsilon, \xi, \rho_j) = 0, \quad j = 2, \ldots, 5.$$  

In what concerns the degree of the above expressions, it follows that the power of $\rho_p$ and $\rho_j$ are all even numbers. Thus by applying a simple substitution of the type $\rho^2_p = \rho^2_p$ and $\rho^2_j = \rho^2_j$, $^0 F_p$ can be reduced to a second degree polynomial expression. Thus one should solve Eqs. (56) and (57) with respect to the extension of the actuators in order to find the possible angular travels, i.e., $\varepsilon$, and $\xi$, which can be readily transformed to $\varepsilon$ and $\xi$. Figure 5 represents an example for the constant-position workspace where the workspace is the whole surface of the sphere except the regions which do not include the arrows.

It should be noted that the obtained solutions for $\varepsilon$ and $\xi$ cannot be plotted along the two constraint circles since they are not decoupled. To do so, we use a spherical representation which is notationally depicted in Fig. 4. Then by applying the tan-half substitution for $\varepsilon_i = \tan \left( \frac{\varepsilon}{2} \right)$ and $\xi_i = \tan \left( \frac{\xi}{2} \right)$, one obtains:

$$^0 F_p (\varepsilon, \xi, \rho_p) = 0.$$  

The above corresponds to the principal limb and applying the same procedure explained in [12] for obtaining the forward kinematic expressions for other limbs, one can readily find the corresponding expressions for the other four limbs:

Thus by applying a simple substitution of the type $\rho^2_p = \rho^2_p$ and $\rho^2_j = \rho^2_j$, $^0 F_p$ can be reduced to a second degree polynomial expression. Thus one should solve Eqs. (56) and (57) with respect to the extension of the actuators in order to find the possible angular travels, i.e., $\varepsilon$, and $\xi$, which can be readily transformed to $\varepsilon$ and $\xi$. Figure 5 represents an example for the constant-position workspace where the workspace is the whole surface of the sphere except the regions which do not include the arrows.

\[\text{Fig. 5: Constant-position workspace for a general 5-RPUR parallel mechanism.}\]

5. Conclusions
This paper investigated the kinematic mapping of the constraint parameters and the forward kinematic problem of a 5-DOF parallel mechanism with identical limb structures performing a 3T2R motion pattern. The mappings from the projective space, Study parameters, to the three-dimensional Euclidean space, and vice versa, were given. Following a similar approach, the first-order kinematics, i.e., velocity mapping was elaborated. By combining the results obtained for both general and first-order kinematic mapping some particular configurations were obtained and physical interpretations were associated to them which would have been difficult without resorting to such a mapping. Moreover, the constant-position workspace for the 5-DOF parallel mechanism under study was investigated. Ongoing work includes the optimum synthesis of the mechanism under study.

**Biography of Authors**

**Mehdi Tale Masouleh** received the B. Eng. and Ph.D. degrees in Mechanical engineering from the Laval University, Québec, Canada, in 2006 and 2010, respectively. Currently, he is a Postdoctoral Fellow under the supervision of Prof. Gosselin in the Robotic Laboratory of Laval University. His research interests are kinematics studies and design of serial and parallel robotic systems with a particular emphasis on the application of algebraic geometry in kinematic modeling of mechanical structures.

**Clément Gosselin** received the B. Eng. degree in Mechanical Engineering from the *Université de Sherbrooke*, Québec, Canada, in 1985, at which time he was presented with the Gold Medal of the Governor General of Canada. He then completed a Ph.D. at McGill University, Montréal, Québec, Canada and received the D. W. Ambridge Award from McGill for the best thesis of the year in Physical Sciences and Engineering in 1988. In 1989 he was appointed by the Department of Mechanical Engineering at *Université Laval*, Québec where he is now a Full Professor since 1997. He is currently holding a Canada Research Chair on Robotics and Mechatronics since January 2001.

His research interests are kinematics, dynamics and control of robotic mechanical systems with a particular emphasis on the mechanics of grasping, the kinematics and dynamics of parallel manipulators and the development of human-friendly robots. His work in the aforementioned areas has been the subject of numerous publications in International Journals and Conferences as well as of several patents and two books. He has also been an associate editor of the ASME Journal of Mechanical Design, the IEEE Transactions on Robotics and Mechanism and Machine Theory. He is a fellow of the ASME and a senior member of the IEEE. He received, in 2008, the ASME DED Mechanisms and Robotics Committee Award for his contributions to the field. Clément Gosselin was appointed Officer of the Order of Canada by the Governor General in 2010.
