#### ARTICLE INFO

Keywords: Tricept Cuboid Shape Dexterous Workspace Complex Degrees of Freedom Parallel Manipulators Genetic Algorithm Method

#### ABSTRACT

This work intends to deal with the optimal kinematic synthesis problem of Tricept parallel manipulator. Observing that cuboid workspaces are desirable for most machines, we use the concept of effective inscribed cuboid workspace, which reflects requirements on the workspace shape, volume and quality, simultaneously. The effectiveness of a workspace is characterized by the dexterity of the manipulator all over its workspace. Tricept has a complex degree of freedom, i.e. both rotational and translational DoF, therefore its performance indices depend on the singular values of the dimensional in-homogeneous Jacobian. Here, we divide the Jacobian entries by units of length, thereby producing a new Jacobian that is dimensionally homogeneous. By multiplying the associated entries of the twist array to the same length, we made this array homogeneous as well. This implies some sort of tradeoff between position and orientation components of the twist array. An optimal design problem, including constraints on actuated and passive joint limits, is then formulated. This problem is a constrained nonlinear optimization problem. Therefore, Genetic Algorithm toolbox of Matlab is adopted to solve the problem.

#### 1. Introduction

Parallel manipulators have received extensive attention over the last two decades for their potential superior properties, such as low inertia, high stiffness, high precision and high load carrying capacity [1-3]. However, they suffer from smaller workspace relative to their serial counterparts. Choosing a set of geometric parameters so as to achieve optimal performance is of vital significance in robotics research [4-6]. Among all kinematic measures, workspace is the most important index in the design of a parallel manipulator. A parallel manipulator designed only for maximum workspace volume may not however be a good design in practice. It is possible that the manipulator with maximum workspace has undesirable kinematic characteristics such as poor dexterity and irregular shape [7]. In order to avoid undesirable effects of workspace volume maximization, researchers introduced other

performance indices into the optimal design problem [8-10]. Li and Xu [8] optimized Delta as a translational parallel manipulator to have a good conditioning index and stiffness. In [10] 3-PRS optimization to achieve maximum dexterous workspace (MDW) was performed. In [7] MDW of Tricept manipulator was addressed, using Genetic Algorithm (GA) method, while the shape of the workspace is much more important in some applications of robots. Liu and Li addressed the optimal effective regular workspace of parallel manipulators [11].

In this paper, the workspace of Tricept is parameterized using some design parameters. Moreover, some geometric constraints are considered in the problem. Because of nonlinear discontinuous behavior of the problem, GA is used to optimize the workspace. For the workspace of the manipulator, we evaluate local conditioning indices (LCI) and minimum singular values (MSV). Then, we maximize the workspace of the manipulator subject to the constraints on LCI and MSV. In practice, although a cuboid workspace is desirable, parallel manipulators often have irregular-shaped workspaces due to their complex kinematic structures. Tricept does not exempt from this rule. A design solely for maximal workspace may not have the maximal cuboid workspace. Therefore, the optimal design problem is formulated to maximize the volume of inscribed cuboid in the workspace subject to dexterity constraints; namely, LCI and MSV. Furthermore, a design purely for maximal inscribed cuboid (MIC) workspace may also lead to smaller workspace volume. Therefore, we use the concept of effective inscribed cuboid workspace, which reflects requirements on the workspace shape, volume and quality, simultaneously. That is, we employ a linear combination of measures on the volume of workspace and MIC in the objective function, while keeping the above mentioned quality constraints.

#### 2. Tricept Mechanism

One of the most famous parallel manipulators with machine tool application is Tricept family which has both rotational and translational degrees-of-freedom (dof) [12]. A comparison study is performed by Pond [13] between Tricept and some other parallel robots with the same number of degrees of freedom, such as, 3-PRS and 3-RPS by considering their condition numbers and maximum and minimum singular values. The manipulator has three actuated limbs which connect the base to the moving platform. Each of these limbs consists of a spherical-prismatic-spherical (SPS) kinematic chain, where only the prismatic joint is actuated. Alternatively, one of the spherical joints can be replaced by a universal joint. Moreover, a passive prismatic-universal (PU) limb connects the center of the moving platform to the base. We attach frames  $\{P\}$ (uvw) and  $\{O(xyz)\}$  to the moving and base platforms, respectively. When the moving platform is parallel to the base, the two revolute axes of the universal joints of the center passive leg are parallel with the base frame's x and y axes, respectively.

Siciliano [14] studied the kinematics and manipulability of Tricept. Pond and Corretero formulated its square dimensionally homogeneous Jacobian matrices based on three independent coordinates of three nodes of the moving platform [15]. Architectural optimization of Tricept was studied by Zhang and Gosselin [16]. They used GA to optimize the stiffness and end-effector (EE) accuracy.

#### 2.1. Velocity Analysis

The loop closure equation for the  $i^{th}$  leg can be written

as:

$$\boldsymbol{c} + \mathbf{R}(\boldsymbol{a}_i + \boldsymbol{d}) = b_i \boldsymbol{n}_{bi} + l_i \boldsymbol{n}_{li}$$
(1)

where c and d are the vectors from O to C and C to P, respectively. While **R** is rotation matrix carrying frame

{*P*} into an orientation coincident with that of frame {*O*};  $a_i$  is the position vector from P to  $A_i$  in frame {*P*};  $b_i$  is the position vector of point  $B_i$  in the global frame. Moreover,  $n_{bi}$  and  $n_{li}$  are the unit vectors showing the directions of vectors  $b_i$  and  $l_i$ , respectively.

Figure 1: Tricept structure and geometric model.

Taking the first time derivative of Eq.1 yields:

$$\dot{\boldsymbol{c}} + \boldsymbol{\omega}_p \times (\mathbf{R}(\boldsymbol{a}_i + \boldsymbol{d})) = l_i \boldsymbol{n}_{li} + \boldsymbol{\omega}_l \times l_i \boldsymbol{n}_{li}$$
(2)

where  $\omega_p$  and  $\omega_l$  are the angular velocity vectors of the EE and limb, respectively. Pre-multiplying both sides of Eq.2 by  $n_{li}^{T}$ , upon simplifications and written them for for *i*=1...3, yields:

$$\mathbf{J}^{-1}\dot{\mathbf{x}} = \dot{\boldsymbol{q}} \tag{3}$$

where  $\dot{\mathbf{x}} = \begin{bmatrix} \dot{c} & \dot{\psi} & \dot{\theta} \end{bmatrix}^T$  is the three dimensional twist vector;  $\dot{\mathbf{q}} = \begin{bmatrix} \dot{l}_1 & \dot{l}_2 & \dot{l}_3 \end{bmatrix}^T$  is the three dimensional actuator velocity vector and  $\mathbf{J}^{-1}$  is the inverse Jacobian matrix, namely;

$$\mathbf{J}^{-1} = \begin{bmatrix} n_{l1z} & (\mathbf{R}(\boldsymbol{a}_{1} + \boldsymbol{d}) \times \boldsymbol{n}_{11})_{x} & (\mathbf{R}(\boldsymbol{a}_{1} + \boldsymbol{d}) \times \boldsymbol{n}_{11})_{y} \\ n_{l2z} & (\mathbf{R}(\boldsymbol{a}_{2} + \boldsymbol{d}) \times \boldsymbol{n}_{12})_{x} & (\mathbf{R}(\boldsymbol{a}_{2} + \boldsymbol{d}) \times \boldsymbol{n}_{12})_{y} \\ n_{l3z} & (\mathbf{R}(\boldsymbol{a}_{3} + \boldsymbol{d}) \times \boldsymbol{n}_{13})_{x} & (\mathbf{R}(\boldsymbol{a}_{3} + \boldsymbol{d}) \times \boldsymbol{n}_{13})_{y} \end{bmatrix}$$
(4)

#### 3. Workspace Analysis

In this section, we study the workspace of a Tricept manipulator numerically.

#### 3.1. Algorithm

In order to generate the workspace of a Tricept parallel manipulator, we divide the three dimensional  $\psi$ - $\theta$ -Z workspace of the moving platform into a series of sub-workspaces that are parallel to  $\psi$ - $\theta$  plane. Then a numerical searching method, was introduced in [17, 18], is adopted here to determine the boundary of the sub-workspaces. Finally, the volume of workspace is calculated quantitatively.

#### 3.2. Geometric Constraints

These constraints include the actuators lengths (*l*) and the spherical and universal joints limitations. It is simple to calculate the cone angle of joints ( $\zeta$ ) by using the geometric constraints and kinematics relations, as shown in figure 2. The geometric constraints of the Tricept are given in Table 1.

#### **3.3.** Design Constraints

In order to guarantee the workspace to be effective, constraints on the dexterity indices are introduced to characterize quality of the workspace.

Figure 2: Geometric constraints of Tricept robot.

Table 1: Geometric constraints of the Tricept manipulator.

Actuator Length	ζ	d	r <sub>b</sub>	ra
( <i>mm</i> )	(deg)	(mm)	(mm)	(mm)
400-750	±60	0-200	300-500	200-300

Condition number is quite often used as an index to describe the dexterity of a robot and the distance of a pose from a singularity. The condition number also measures the magnitude of the relative error of the wrench introduced by the relative error in joint torques and reflects the sensitivity of the wrench due to joint torque error. Similarly, the use of minimum allowable singular value restricts the workspace to poses where the manipulator moves at a minimum allowable speed. Here, we optimized Tricept for dexterity measures, namely; the inverse of condition number as a LCI and the MSV.

In engineering applications, we often attach a great importance to study the dexterous workspace (DW) of a manipulator rather than the reachable workspace. Moreover, kinetostatic performance or dexterity measures how well the system behaves with regard to force and motion transmission. Several dexterity criteria could be taken into account; such as service angle, manipulability, MSV, maximum singular values and condition number [19]. Condition numbers and MSV of the Jacobian matrices are known as a kinetostatic performance index of parallel manipulators [20, 21]. Indeed, in order to determine the condition number and MSV of the Jacobian matrices, we must order their singular values from largest to smallest. However, in the presence of positioning and orienting tasks, three of these singular values, namely, those associated with positioning, are dimensionless; while those associated with orientation have units of length, thereby making impossible such an ordering.

Ranjbaran and Angeles [22] resolved this inconsistency by defining a characteristic length, by which they divided the Jacobian entries that have units of length, thereby producing a new Jacobian that is dimensionally homogenous. Ma and Angele [20] introduced another ratio called natural length and used it for design optimization. Chablat et al., used characteristic length to determine the design parameters of a planar parallel mechanism with PRR chains to have an isotropic condition [23]. Gosselin [24] introduced a method for formulating dimensionally homogenous Jacobian matrix for a planar mechanism with one rotational and two translational dof. The Jacobian matrix relates the actuator velocities to the velocities of the x and vcoordinates of two points on the EE platform. Kim and Ryu [25] furthered this work by using the velocities of three points on the EE platform to develop a dimensionally homogenous Jacobian matrix. Pond and Corretero [15] further developed this method by using three independent coordinates of three points on EE platform. Moreover, Angeles [26] introduced engineering characteristic length for a rigid body transformation matrix to make it homogenous. Mansouri [27] used power transition concept to make the Jacobian homogeneous. Hosseini et. al. [7] resolved the inconsistency by defining a weighting factor, by which they divided the Jacobian entries that have units of length, thereby producing a new Jacobian that is dimensionally, homogeneous. Moreover, one might choose different weighting factors for different coordinates of twist array and the associated columns of the Jacobian matrix, even those with the same units.

Dividing the second and the third columns of the Jacobian matrix of Eq. 3 by a length and multiply the second and the third coordinates of the twist vector to the same length leads to the following dimensionally homogeneous relation:

$$\begin{bmatrix} \mathbf{R}(\mathbf{a}_{1}+\mathbf{d}) \times \mathbf{n}_{11} \\ \mathbf{n}_{l1z} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{1}+\mathbf{d}) \times \mathbf{n}_{11} \\ \mathbf{n}_{l2z} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{2}+\mathbf{d}) \times \mathbf{n}_{12} \\ \mathbf{n}_{l2z} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{2}+\mathbf{d}) \times \mathbf{n}_{12} \\ \mathbf{n}_{l3z} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{n}_{13} \\ \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{n}_{13} \\ \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{n}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{n}_{l3} \\ \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{n}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{n}_{l3} \\ \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{n}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{d}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{d}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{d}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{d}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{d}) + \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{d}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{d}) + \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{d}_{3}+\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{d}) + \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{d}) + \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{d}) + \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{d}) + \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{d}) + \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{d}) + \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{d}) \times \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{d}) + \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{d}) \times \mathbf{R}(\mathbf{d}) + \mathbf{R}_{l3} \\ \mathbf{R}(\mathbf{d}) + \mathbf{R}(\mathbf{d}) + \mathbf{R}_{l3} \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{d}) \times \mathbf{R}(\mathbf{d}) + \mathbf{R}(\mathbf{d}) + \mathbf{R}(\mathbf{d}) + \mathbf{R}(\mathbf{d}) \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\mathbf{d}) \times \mathbf{R}(\mathbf{d}) + \mathbf{R}(\mathbf{d})$$

Physically, this implies some sort of tradeoff between position and orientation components of twist array. This weighting factor should be constant throughout the workspace. The designer should choose the weighting factor based on the application of the mechanism. For example, in a milling operation as depicted in Figure 3, the radius of end-milling cutter is the length that relates the tangential cutting force to the torque and should be chosen as the weighting factor by the designer. It is noteworthy that the same factor relates angular velocity to linear velocity. Moreover, one might compare one unit of the linear velocity with  $m \times l$  units of angular velocity around x axis and  $n \times l$  units of angular velocity around y axis. So, we can assign different weighting factors to the different coordinates of the twist vector

Figure 3: Weighting factor in a milling operation.

#### 4. GENETIC ALGORITHM OPTIMIZATION

One of the drawbacks of parallel manipulators is their limited workspace. It is more limited in the presence of constraints such as dexterity, isotropy and joints limits. Clearly the optimal design problem is a constrained nonlinear optimization problem. Here, we resort to a direct search method; namely, GA which was widely studied as a global optimization technique [28-31]. The algorithm is robust, i.e., it normally works regardless of irregularities of the objective function.

#### 4.1. Setup of the GA Optimization

#### • Design Variables

There are three parameters in the optimization process which define the manipulator architecture. They are the moving and base platform radiuses ( $r_a$  and  $r_b$ ), and the upper part of middle link length (d) whit their boundaries as given in Table 1.

#### • GA Optimization Setup

In order to apply the GA for optimization, six fundamental issues are required to be determined, i.e., the chromosome representation, selection function, genetic operators, population size, termination criteria, and evaluation function [30]. For the current optimization problem, the objective functions are chosen as the evaluation functions. Moreover, actuators length, joints limitations are the geometric constraints, while lower bound of MSV and LCI are the design constraints.

#### 5. Case Study

## 5.1. Maximal Workspace Volume with Geometric Constraints

Here, the workspace is parameterized using three design parameters; namely, the moving and base platform radiuses ( $r_a$  and  $r_b$ ) and the upper part of passive link length (d), all summarized in the vector form as  $\lambda = [r_a \ r_b \ d]^T$ .

Then, using GA method, the workspace is optimized subjects to some geometric constraints as given in table 1. Therefore, our optimization problem yields to:

$$V = Max(V(d, r_a, r_b))$$
(6)

Subject to:

 $200 < r_a < 300, 300 < r_b < 500, 20 < d < 200, 2-400 < Actuator Length(l) < 750, -60 < \zeta_i < 60 deg$ 

in which V is a function to calculate the workspace volume. Solving this optimization problem by GA leads to the data given in Table 2, in which the maximal workspace is  $858.9751 \text{ mm.Rad}^2$ .

#### 5.2. Constraints Evaluation

In the followings, we evaluate non-geometric constraints; namely, MSV and the inverse of condition number of the Jacobian as LCI for different elevation ranges of the foregoing manipulator. The workspace volume versus lower bound of LCI and MSV is depicted in figure 4. As the minimum permissible limit on singular values is increased, the workspace continues to be reduced. Moreover, as the minimum permissible limit on LCI is increased, the workspace continues to be reduced, as well.

Table 2: Maximal workspace volume with geometric constraints.

No. of	$V^{*}$	d	$r_b$	<i>r</i> <sub>a</sub>
Iteration	$(mm.Rad^2)$	(mm)	( <i>mm</i> )	<i>(mm)</i>
51	858.9751	20	300	200

Considering any minimum permissible limit on singular values leads to the workspace with lower bound for EE velocities; while considering the minimum permissible limit on LCI leads to the manipulator as close as to isotropic conditions. For the workspace of the manipulator, depicted in Table 2, considering the minimum permissible limit on LCI to be greater than or equal to 0.6 and MSV to be greater than or equal to 1, yields to the workspace of Figure 5, with the volume of 267.4887Rad<sup>2</sup>.mm. This volume is 68.86% smaller than the original one, without considering these constraints.

Figure4: Maximal workspace volume verses the minimum permissible limits on LCI and MSV.

Figure 5: Sub-workspace of the maximal workspace by limiting MSV and LCI.

## 5.3. Dexterous and High Velocity Workspace Volume

In the followings, the workspace volume of the Tricept is optimized by constraining the MSV and LCI of the Jacobian matrix to be within a desired range along with the geometric constraints of Table 1. Therefore, the optimization problem can be re-written as:

$$W^* = Max(V(c, r_a, r_b))$$
(7)

Subject to:

 $I-LCI \ge 0.6, \ \sigma_{min} \ge 1$ 2-200<  $r_a < 300, \ 300 < r_b < 500, \ 20 < d$ 

-----

<200, 400<Actuator Length(l)<750,

$$-60 < \zeta_i < 60 deg$$

Solving this problem by GA leads to the data given in Table 2, in which the maximal workspace is  $369.4139 \text{ mm.Rad}^2$ , which is 38.1% more than that volume of Figure 5. This workspace is illustrated in Figure 6.

Table 3: Optimization results for design constrained workspace.

No. of	W <sup>*</sup>	d	r <sub>b</sub>	r <sub>a</sub>
Iteration	(mm.Rad²)	(mm)	(mm)	(mm)
52	369.4139	127.293	454.518	203.052

Figure 6: Maximal dexterous workspace (DW).

#### 5.4. Effective Inscribed Cuboid Workspace

As it is depicted in the Figure 6, MDW might lead to an irregular shape. Therefore, it is essential to reach a maximal workspace as close as to a regular shape such as a cuboid or a cylinder. In the following, using GA method, we will find the MIC. It is noteworthy that we will give different weights to the rotational dof than the translational one.

5.4.1. Maximal Inscribed Cuboid

Here, we use an iterative search algorithm to find the MIC in the workspace. This method includes the following steps:

Step 1. Cuboid center determination: Due to symmetry, the coordinates of the cuboid center, without loosing of generality, is assumed as  $\psi=0$ ,  $\theta=0$  and Z equal to the average altitude of the EE in the workspace.

*Step2.* A complete rotation of a cuboid around Z axis: For each step, the lengths of the cuboid will be increased incrementally. The largest inscribed cuboid in each step of rotation will be registered.

*Step3*. The MIC: The largest registered cuboid and its related rotation can define the MIC in the DW.

Figure 7 illustrates the MIC in the DW, in which we have the volume of cuboid equal to 88.3362 mm.Rad<sup>2</sup>, and its aspect ratio equal to 208.687. However, the related DW is 307.2612 mm.Rad<sup>2</sup>; some 17% smaller than the MDW of Figure 6. These design parameters is summarized in Table 4.

Table 4: MIC and the design parameters.

No. of Iteration	DWVolume (mm.Rad <sup>2</sup> )	MICVolume (mm.Rad <sup>2</sup> )	A.R.	d	r <sub>b</sub>	ra
51	307.2612	88.3362	208.687	39.542	321.742	202.041

a. MIC in the related DW

### 5.4.2. Maximal Inscribed Cuboid with a Desired

#### Aspect Ratio

Here, using the same algorithm, we find MIC in the DW with a desired aspect ratio equal to 200. Moreover, the MIC in the DW leads to the data of Table 5 which is illustrated in Figure 8. As it is expected, the volume is further decreased to  $83.601 \text{ mm.Rad}^2$ , which only fills 25.13% of the DW volume.

#### 5.5. Effective Inscribed Cuboid Workspace

Here, we employ a linear combination of measures on the volume of workspace and MIC in the objective function, while keeping the above mentioned quality constraints, i.e., the objective function is defined as:

$$V = \max\left(\kappa \frac{W}{W_{max}} + (1 - \kappa) \frac{V_c}{V_{max}}\right)$$
(8)

where,  $w_{max}$  and  $v_{max}$  are the largest workspace and the volume of the MIC, respectively. Also, W and  $V_c$  are the DW and its related inscribed cube volume, respectively.

Moreover,  $\kappa$  is the weight factor for the volume of cuboid and the workspace volume.

Solving this problem for  $\kappa = 0.2$  by GA leads to the data given in Table 6 and the workspace is illustrated in Figure 9. As it is seen, we can increase the volume of the inscribed cuboid with the cost of robot workspace volume.

a. MIC in the related DW

Figure 8: MIC in DW with A.R. 200

Table 5: MIC a	nd the design	parameters	with A.R. 200
----------------	---------------	------------	---------------

No. of	Cube Volume	d	r <sub>b</sub>	ra
51	83.6008	90.401	453.527	200

For this design, the workspace and MIC volume versus lower bound of LCI and MSV are calculated and depicted in Figures 10 and 11, respectively. As the minimum permissible limit on singular values is increased, the DW and MIC continues to be reduced. Moreover, as the minimum permissible limit on LCI is increased, the workspace and MIC continues to be

reduced, as well.

Dexterous Workspace Volume: 339.8771 Rad.mn

Figure 10: DW volume versus design constraints.

#### 6. Conclusion

In this paper the workspace optimization of Tricept was performed. This parallel manipulator has a complex degree of freedom, therefore has leaded to dimensional in-homogeneous Jacobian matrices. Here, we divided some entries of the Jacobian by units of length, thereby producing a new Jacobians that is dimensionally homogeneous. By multiplying the associated entries of the twist array to the same factor, we made this

Figure 11: MIC volume versus design constraints.

array homogeneous as well. For the platform, the workspace was parameterized using some design parameters. Then, using GA method, the workspace was optimized subjects to some geometric constraints. Moreover, LCI and MSV were calculated for the workspace of the manipulator. Finally, we used the concept of *effective inscribed cuboid workspace*, which reflected requirements on the workspace shape, volume and quality, simultaneously. It was shown that by introducing the LCI and MSV as the quality measures throughout the workspace, the performance of the manipulator was improved at the cost of workspace reduction.

#### **Biography of Authors:**

Mir Amin Hosseini is currently PhD student in the Department of Mechanical Engineering, from Babol University of Technology. He received his B.Sc. in Manufacturing Engineering from Tehran Polytechnic University and M.Sc. in

Manufacturing Engineering from Tarbiat Modarres University. His research interests focus on parallel machine tools.

Hamid-Reza M. Daniali is currently an Associate Professor in the Department of Mechanical Engineering, at Babol University of Technology. Dr. Daniali graduated as a Mechanical Engineer at Ferdoosi University in 1965. He

received the M.Sc. in 1968 from Tehran University and in 1995, the Ph. D. degree in Mechanical Engineering from McGill University. His research interests focus on theoretical kinematics and parallel manipulators.
